FINAL PROJECT RUBRIC

Module Code: NPRJ740

Module Name: Project

Programme: Advanced Diploma in Information and Communication Technology

Academic Year: 2026

Lecturer: Dr Silas Verkijika

Assessment Components

Component	Weight
Final Project Documentation	40%
System Implementation	50%
Final Presentation and System Demonstration	10%
Total	**100%**

Assessment Basis

The final project is assessed as an integrated software-development submission comprising:

- the Final Project Report;
- the final submitted GitHub repository and identified release/tag/commit;
- the implemented system and supporting technical artefacts; and
- the final presentation, live system demonstration and technical defence.

The System Implementation is assessed against the final system documented in the report, including the Final Release Scope, requirements, business rules, design, implementation and verification evidence.

The Final Presentation and System Demonstration includes lecturer-selected verification of functionality identified as included in the submitted final system.

PROJECT DELIVERABLE 1: FINAL PROJECT DOCUMENTATION

[40 MARKS]

Criterion	Marks	Assessment standard
1. Project context, problem, purpose and success criteria	**3**	The application context, intended users/client and problem are clearly established. Relevant supporting evidence is presented, the project purpose is coherent and the success criteria are meaningful and verifiable.
2. Solution overview and final scope	**3**	The system boundary and final solution are clearly communicated. Included functionality, excluded/deferred capabilities and known limitations/open issues are distinguished accurately. The context diagram appropriately represents the system and its external interactions.
3. System Requirements Specification	**6**	Functional and non-functional requirements are clear, relevant and appropriately verifiable. Requirement identifiers are used consistently. MoSCoW priorities and release status are meaningfully applied. Important business rules and acceptance criteria are adequately specified.
4. System Design Specification	**12**	The report provides a technically meaningful representation of the final implemented design through appropriate use cases/workflows, architecture, design decisions, class design, interface/interaction design, data design, security/access-control design and deployment/runtime design. Models and diagrams are internally consistent and correspond to the final system.
5. Implementation documentation	**4**	The report explains how the source code is organised and how the important system capabilities are implemented. Relevant APIs, integrations and specialised components are adequately explained without reproducing unnecessary volumes of code.
6. Verification and testing documentation	**6**	The test approach is clearly documented and important requirements/business rules are linked to credible verification evidence. Appropriate successful and failure conditions are reported. Relevant non-functional/security verification and significant defects are clearly documented.
7. System setup and solution evaluation	**3**	The instructions provide sufficient information for a technically competent person to understand how the submitted system is configured and run. The final evaluation explicitly assesses the system against the previously defined Success Criteria using implementation and testing evidence.
8. Technical communication,	**3**	The report is professionally structured, concise and technically understandable. Terminology, requirement identifiers, scope,

consistency and referencing		diagrams, implementation and testing evidence are internally consistent. Sources are appropriately acknowledged and supporting links/material are correctly provided.
TOTAL	**40**	

PROJECT DELIVERABLE 2: SYSTEM IMPLEMENTATION

[50 MARKS]

Criterion	**Marks**	**Assessment standard**	**Cross-reference to Final Report**
1. Functional implementation and requirements alignment	**12**	The submitted implementation provides a sufficiently complete set of capabilities to meaningfully address the stated problem and implements the significant capabilities identified as included in the final release. Core workflows are substantively implemented and important requirements and business rules are reflected in the code. Functionality marked as Included but absent, stubbed or materially incomplete reduces the mark.	Sections **3.2, 4.1, 4.3, 4.4 and 6.2**
2. Code quality and maintainability	**9**	Code demonstrates appropriate organisation, modularity, separation of concerns, naming, readability, reuse and abstraction. Logic is reasonably maintainable and avoids unnecessary duplication, excessive coupling and inappropriate complexity.	Sections **5.3, 5.4 and 6.1**
3. Architecture and technical integration	**7**	The implemented architecture is coherent and corresponds materially to the final architecture described in the report. Major components have appropriate responsibilities and, where applicable APIs, services and external integrations are implemented consistently with the documented design.	Sections **5.2, 5.3, 5.8 and 6.3**
4. Data and state management	**5**	Persistent data or application state is appropriately implemented for the selected technology. The implementation is consistent with	Section **5.6** and relevant requirements

		the documented data model and appropriately handles relationships/references, integrity, validation and consistency.	
5. Security, validation, and failure handling	**5**	Relevant authentication, authorisation, input validation, secrets management and error/failure handling are appropriately implemented for the system context. Implemented controls correspond to those documented in the final report.	Sections **4.3 and 5.7**
6. Testing, verification and technical robustness	**7**	The submitted implementation and supporting test artefacts provide credible evidence that important requirements, business rules and relevant non-functional requirements have been verified. Automated test code, where used, and other verification evidence should correspond to the testing reported in the final report.	Section **7** and relevant requirements from Section **4**
7. Repository, version integrity and reproducibility	**5**	The submitted repository is coherently organised; the assessed version is clearly identifiable by the submitted tag/commit; required source, dependency/build files, and where applicable, migrations/configuration examples and test artefacts are present; and the repository is consistent with the system described in the final report.	Sections **6.1, 8 and 11.1**
TOTAL	**50**		

PROJECT DELIVERABLE 3: FINAL PRESENTATION AND SYSTEM DEMONSTRATION

[10 MARKS]

Criterion	Marks	Assessment standard
1. Project overview and technical communication	**1**	Clearly and concisely presents the problem, purpose, final solution and main technical characteristics within the allocated time.
2. Demonstration of principal system workflow	**2**	Successfully demonstrates a meaningful end-to-end workflow using the final submitted system. The

		demonstrated workflow should show substantive functionality rather than isolated screens.
3. Lecturer-selected functionality and robustness verification	4	Successfully demonstrates functionality selected by the lecturer from the submitted Final Release Scope, functional requirements or business rules. The lecturer may also require an associated validation, access-control, alternative-flow, boundary, error or failure condition. Students must be prepared to demonstrate any capability identified as included in the final release.
4. Explanation of engineering decisions	**1**	Clearly explains important architecture, technology or implementation decisions and provides an appropriate rationale for the choices made.
5. Technical understanding and defence	**2**	Responds appropriately to questions about the implementation, code, architecture, testing, limitations or demonstrated functionality and demonstrates clear technical understanding of the submitted work.
